Armaaruss Military Drone and Soldier Detection System

(Armaaruss Model Sys Version 1 - build 2)
by Anthony of Boston

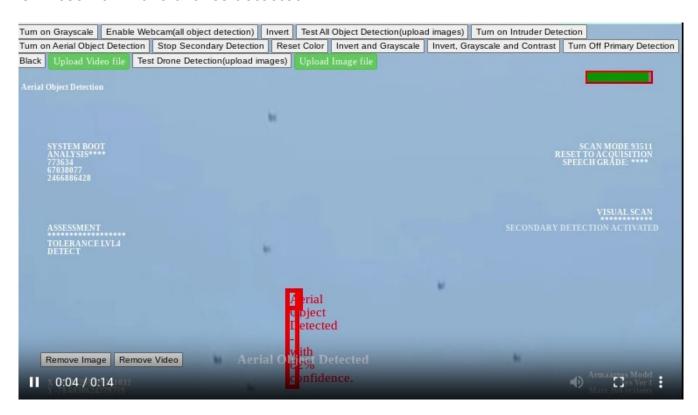

This document contains the javascript source code for the visual component of Armaaruss, which is a military detection program that can detect drones and enemy soldiers. The HTML code can simply be copy and pasted from the document. (download the document before copying and pasting) This is the first model sys version of Armaaruss (build 2), and contains new programming techniques for object detection. This code puts both aspects of drone and human detection into one application. Here is look at the applications's interface. The images show how the application can detect Russian and Chinese Kamikaze drones

Russian drone detected:

Chinese Kamikaze drones detected

This drone and soldier detection javascript application has multiple functionalities. It comes with both a primary and secondary detection. The primary detection(the white bounding box) is the basic object detection using the

webcam of one's device. However, the primary detection does not react to color calibration, meaning that the output is the same regardless of whether the screen or frame is bright or dark. The secondary detection's output is tied to color calibration, meaning that using the different filters used to alter the appearance the frame/video will affect the output of the secondary detection. You can test this on the app by clicking the "Black" button. The screen will turn black, but primary detection can still be activated, while secondary detection can no longer display a bounding box. Secondary detection is functional, but cannot see or detect anything because the screen is black—it is essentially detecting a black image, while primary detection is still processing video output.

*just a quick note. This secondary detection aspect tied to color calibration is not currently applicable to the video upload feature in this build 2. You can apply secondary detection to uploaded videos, but it will not react to color calibration. This feature will be added to video uploads in the future. The rest of the features in this build, such as webcam and image upload, has the color calibration tied to secondary detection.

The breakthrough here is that the javascript code for the secondary detection is treating the webcam video output as an image, and not a video. A good way to understand secondary detection is to imagine continuously uploading a new image file every second. With tensorflow's default object detection code for detecting objects on various images, uploading a new image file every second is what one would have to achieve in order to match the processes of secondary detection. This application entitled "Armaaruss Military Drone and Soldier Detection System" manipulates tensorflow script to have every frame detected and treated as an image, with the bounding boxes rendered and removed with each frame. This is what makes Armaaruss's vision component different from other object detection applications.

Thus, it is inferred that secondary detection can be used to detect object in different scenarios without having to re-train the models over and over again. This provides the possibility that drones can also be detected at night by applying the "invert" and other filters to color calibrate the frame that contains the video output. The primary detection box is "white", while the secondary detection box is "red."

This Armaaruss application, while not quite optimized for mobile use, comes with an aerial object detection system and intruder detection system that uses a beeping sound and voice to indicate when these have been detected. The aerial object detection system will beep when an aerial object is located. The longer an aerial object is hovering near you, the longer the beeping noise. For soldiers, this could mean that a drone is targeting them. Ideally, soldiers would use the app on their cell phones and attach the device to the top area of their vehicles or to their body while sleeping in the trenches. Keep mind that sim cards must be removed and cell phone wireless connectivity must remain "off" in combat environments. Before deployment, soldiers should connect to wifi and start the app. Once the app is started, a soldier can then disable wifi and leave the app running as he/she is deployed into a combat zone. For detecting aerial objects in

combat, android phone should be mounted to the top of the backpack or top of the helmet.

In civilian environments, the cell phone, with wireless turned on, could be placed on rooftops. With internet access, a user could view the aerial scene remotely with facebook live

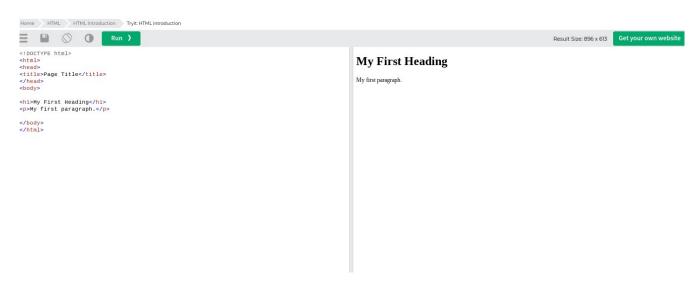

The Intruder Detection application will beep when an intruder is detected. The app will also emit voice alert, saying "intruder detected" upon detection of an intruder. This app allows phones to be mounted in various places, to which it can detect when an intruder is in the area. This can be used in clearing and counter insurgency operations. This is also useful for the civilian population against thugs and other criminal elements in urban environments. The app can prevent ambush attacks. The phone could be placed in the cracks of walls and other discreet locations. With internet access, a user could view the scene remotely with facebook live and see when intruders have gained unauthorized access.

For testing, one can copy and paste this html code at a website called https://www.w3schools.com/html/tryit.asp?filename=tryhtml_intro

Just copy and paste the following HTML code on the left side in order to test the object, intruder, and drone detection on your webcam. (ends on page 58)
